

# **2-6 NOVEMBER 2020**

## **10. WIDE-FIELD IMAGING** Jack F. Radcliffe

University of Pretoria (RSA) & Manchester (UK)

jack.radcliffe@up.ac.za/@radcliffe (Mattermost)

### Outline

- Motivation i.e. why do we want to image degrees of the sky with VLBI? 1.
- 2. Challenges
- Calibrating wide-field VLBI data\* 3.
  - a. Phase referencing
  - b. Self-calibration
  - c. Primary beam correction
- 4. Conclusions / take-away points

\*In particular, highlight the nuances between standard calibration and wide field + how techniques developed for wide-field VLBI can be applicable to standard VLBI observing!

#### **JACK RADCLIFFE**

## Wide-field VLBI - definition

### What do we mean by wide-field VLBI?

- Simply concerned with *imaging the entire primary* beam of a VLBI array
- See multiple science targets in one observations
- Historically, much easier for shorter baseline instruments

What are the advantages of imaging the entire primary beam?

#### **1. MOTIVATION**

### Some science examples - supermassive black hole binaries

#### WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

#### **JACK RADCLIFFE**

Radcliffe+ in prep.

### **Gravitational lenses**

- Rare (~0.3% of VLBI sources)
- Independently measure the sub-structure mass-function within galaxies.
- Unique probing of the low-mass end of the dark • matter halo mass-function
- High resolution of VLBI can constrain lens models

#### WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

### **SPINGOLA ET AL. 2018, 2019**

#### MOTIVATION

### **Gravitational lenses**

- Spingola+19 searched 3640 mJIVE-20 survey sources
- Found two gravitational lenses!

**JACK RADCLIFFE** 

WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

## **AGN surveys**

- VLBI detection sure indicator of AGN (high brightness temperatures  $> 10^{5}$  K)
- Use VLBI to understand nature of radiomode AGN
- Other AGN identification methods are notably incomplete or contaminated.
- Note there are many more wide-field VLBI use-cases too (e.g. ISM of nearest galaxies; Morgan+13, supernovae; Radcliffe+19 etc.)!

### E.G. MIDDELBERG ET AL. 2011, 2013, HERRERA-RUIZ ET AL. 2017,

#### **RADCLIFFE ET AL. 2018**

COSMOS-VLBA – 2 degree survey (Herrera-Ruiz+17, 18)

WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

### Imaging the entire primary beam - challenges

#### **Image sizes** ٦.

- Assuming ~0.5 degree field-of-view (25m) telescopes at 1.4 GHz) w/ Nyquist sampling
  - Very Large Array (VLA) A-configuration (1.4" resolution) -  $\sim 1.4 \times 10^7$  pixels
  - Very Long Baseline Array (VLBA) (~6 mas resolution) -  $\sim 1 \times 10^{11}$  pixels

#### **2. CHALLENGES**

### Imaging the entire primary beam - challenges

### 2. Smearing

#### NVSS (VLA) - short baselines

**JACK RADCLIFFE** 

#### WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

Edge of PB massively smeared

#### e-MERLIN - long baselines

Centre of PB no smearing

Image credit - T. Muxlow

#### **2. CHALLENGES**

### Imaging the entire primary beam - challenges

#### **Non-coplanarity or the** *w* term 3.

#### e-MERLIN - source 7.5' from pointing centre

\* computationally expensive

#### Severity of these issues $\propto$ baseline length & distance from phase centre

**JACK RADCLIFFE** 

Ideal RIME

$$\mathsf{V}(u,v) = \iint_{lm} \mathsf{B}(l,m) \exp\left\{-2\pi i \left[ul + vm + w \left(n-1\right)\right]\right\}$$

#### **2. CHALLENGES**

### **Solutions - standard** 'wide-field' correlation

Field-of-view due to smearing

 Correlate at high temporal & frequency resolution

*Result* - monolithic and huge data set which is 99.99999% noise

- This huge single data set is often TBs\* in size
- Often have to shift to different positions in the primary beam which is inaccurate using standard software.

\*Note: a 22 telescope, 12 hour EVN observation @ 1 Gbps > 15 TB

- Split data into time chunks
- 2. Correlate each chunk at very high time & frequency resolution to prevent smearing
- Copies & phase shift to multiple locations in 3. primary beam
- 4. Average in time & frequency

*Result -* you receive lots of small (in FoV and size) data sets at different positions across the primary beam so it's easily parallelisable!

 Choice of phase centres is up to the user and could cover entire primary beam, or just some known sources of interest e.g. VLA positions etc.

#### MORGAN ET AL. 2011, DELLER ET AL . 2011, KEIMPEMA ET AL . 2015

- Split data into time chunks
- 2. Correlate each chunk at very high time & frequency resolution to prevent smearing
- 3. Copies & phase shift to multiple locations in primary beam
- 4. Average in time & frequency

*Result -* you receive lots of small (in FoV and size) data sets at different positions across the primary beam so it's easily parallelisable!

 Choice of phase centres is up to the user and could cover entire primary beam, or just some known sources of interest e.g. VLA positions etc.

## **Calibrating wide-field VLBI data**

- different from standard VLBI data processing,
  - a. Applying solutions in phase referencing
  - **b.** Self-calibration
  - c. Primary beam corrections

much easier.

Calibrating wide-field VLBI data is much easier than you'd think. There are three areas that are

• In addition, there are many pipelines that have been developed (e.g. rPICARD, Janssen+19), or in development (e.g. cm-VLBI pipeline & EVN CASA pipeline), that can make standard calibration

#### **3. CALIBRATING WIDE-FIELD VLBI DATA**

## A shameless plug - the cm-VLBI pipeline

- Currently does the following,
  - A priori calibration for EVN & VLBA data (e.g.  $T_{sys}$ , gaincurves, ionospheric dispersive delays)
  - moment)
  - Support for use on HPC clusters controlled by SLURM / PBS Pro (+ usable on local machines)
- In development,
  - Primary beam correction schemes
  - Multi-source self-calibration (and direction dependent calibration too)
  - Parameter automation (e.g. source finding, calibration solution intervals etc.)

**JACK RADCLIFFE** 

 cm-VLBI pipeline based in CASA (v5.7+/6.1+) currently in development (current v0.8) - <u>https://github.com/</u> <u>jradcliffe5/VLBI\_pipeline</u> - it needs some testers please :)! Nb. it's modular so works with other pipelines.

- Fully parallelised a priori, flagging, phase referencing, and self-calibration via casampi (continuum only at the

Built for wide-field VLBI surveys, but direction-independent calibration works for normal data too.

#### **3A. PHASE REFERENCING**

### **Phase referencing**

**JACK RADCLIFFE** 

- Typically, one phase centre will contain the phase, bandpass and fringe finders sources.
- Most importantly standard VLBI calibration applies
- Calibration tables & flagging tables derived can then be applied to ALL other target fields
- Easily parallelisable so calibration is very quick
- Parallelisation implemented using casampi in cm-VLBI pipeline

#### **3A. PHASE REFERENCING**

### **Phase referencing**

**JACK RADCLIFFE** 

- Typically, one phase centre will contain the phase, bandpass and fringe finders sources.
- Most importantly standard VLBI calibration applies
- Calibration tables & flagging tables derived can then be applied to ALL other target fields
- Easily parallelisable so calibration is very quick
- Parallelisation implemented using casampi in cm-VLBI pipeline

## **Self-calibrating VLBI data**

- Atmospheric effects correlated on short baselines but not on longer baselines (>500 km)
- Often uncorrelated at different locations within target field too...
- Also, the number density of VLBI sources (and their flux densities) lower due to the 'resolving out'/ spatial filtering effect.

**JACK RADCLIFFE** 

#### In-beam phase referencing

- Put a phase-centre on a bright source within the target field and use this to derive selfcalibration solutions.
- Then, apply solutions to all other phase centres.
- However, only some target fields have bright enough detections so...

**JACK RADCLIFFE** 

**Bright VLBI detection**

MSSC S/N ~ 113

![](_page_30_Picture_12.jpeg)

![](_page_30_Picture_13.jpeg)

## **MSSC - not just for wide-field data sets**

- Standard VLBI targets just a small FoV in the centre that may not provide enough S/N for self-calibration, **but** there's other radio sources in the FoV.
- Use multiple phase centre correlation on other potential sources in the primary beam
- Then you may have enough S/N to selfcalibrate VLBI data-set
- Plus you may find something interesting...

![](_page_31_Picture_8.jpeg)

#### Phase centres

### The primary beam problem - the final frontier for wide-field imaging

- field radio observations.
- p and q,

![](_page_33_Figure_4.jpeg)

• Primary beams are the most ubiquitous direction dependent effect (DDE) that affects all wide-

Recap of the Radio Interferometry Measurement Equation (RIME; Smirnov+11) for antennas

![](_page_33_Picture_11.jpeg)

![](_page_33_Figure_12.jpeg)

![](_page_33_Figure_13.jpeg)

![](_page_33_Picture_14.jpeg)

## The primary beam problem - homogeneous arrays

- voltages.
- so  $E(t, l, m) \equiv E(l, m)$ .

gridded so their projected baseline vectors form the *uv* plane,

$$V(u, v) \approx \iint_{lm} B_{app} \exp\left\{-2\pi i \left[ul + vm + w(n-1)\right]\right\} dldm$$

• Assume DIEs (G) are calibrated and no other DDEs are present so E are just the primary beam

• For an homogeneous array e.g. MeerKAT, VLA, ASKAP etc. standard assumption is that the primary beam for each telescope is identical ( $E_p = E_q = E$  for all p, q) and non-varying with time

• This means that each baseline observes the same apparent brightness distribution thus,  $B_{app} = EBE^{H}$ 

• Standard imaging algorithms recover an image by *αssuming that* each baseline observes the same apparent brightness distribution / common sky. Due to this, all of the baselines can be

![](_page_34_Picture_13.jpeg)

### Homogeneous arrays

- This is our standard imaging problem and can gridded, inverted, and de-convolved to recover B<sub>app</sub>.
- We can then recover the true sky brightness distribution via,

$$\mathsf{B}(l,m) = \frac{\mathsf{B}_{app}}{\left| \boldsymbol{E}(l,m) \right|^2}$$

- Images generated will simply be the true brightness attenuated by some power beam
- Thus the true source flux density can be recovered by dividing the image with the power beam response.

#### The GOODS-N field as seen by the VLA

![](_page_35_Picture_10.jpeg)

![](_page_35_Picture_12.jpeg)

### Homogeneous arrays

- This is our standard imaging problem and can gridded, inverted, and de-convolved to recover B<sub>app</sub>.
- We can then recover the true sky brightness distribution via,

$$\mathsf{B}(l,m) = \frac{\mathsf{B}_{app}}{\left| \boldsymbol{E}(l,m) \right|^2}$$

- Images generated will simply be the true brightness attenuated by some power beam
- Thus the true source flux density can be recovered by dividing the image with the power beam response.

#### The GOODS-N field as seen by the VLA

![](_page_36_Picture_10.jpeg)

WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

![](_page_36_Picture_12.jpeg)

### Heterogeneous arrays

- Not so simple for a heterogeneous array. Big issue comes from the following,
  - $\mathsf{B}_{\operatorname{app},pq} = \mathbf{E}_p \mathsf{B} \mathbf{E}_q^H \neq \mathsf{B}_{\operatorname{app},pq} \quad \text{for all } p,q$
- i.e. each baseline does not observe the same apparent brightness distribution
- This manifests as a direction-dependent, antenna independent, and dominant, amplitude (and phase...) error. e.g.

![](_page_37_Figure_6.jpeg)

**JACK RADCLIFFE** 

#### WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

![](_page_37_Figure_12.jpeg)

Dec (J2000)

![](_page_37_Picture_13.jpeg)

![](_page_37_Picture_14.jpeg)

![](_page_37_Picture_15.jpeg)

![](_page_37_Picture_16.jpeg)

### Heterogeneous arrays

- limit dynamic range quite close to the pointing centre.
- Below is a simple simulation of e-MERLIN-A (approx. homogeneous) and e-MERLIN-B range of 1000 at different offsets from pointing centre.

![](_page_38_Figure_4.jpeg)

**JACK RADCLIFFE** 

• This is more of a problem for very heterogeneous arrays (e.g. the EVN) and can drastically

(heterogeneous with two telescope sizes) arrays observing on a point source with dynamic

![](_page_38_Picture_11.jpeg)

![](_page_38_Picture_12.jpeg)

### Heterogeneous arrays

• This can be even more severe for EVN arrays:

Simulation name	Stations	$N_{\mathrm{ant}}$	$N_{\rm pb,uni}$
e-MERLIN-A	Jb-2, De, Kn, Pi, Da	5	1
e-MERLIN-B	Jb-1, Dc, Kn, Pi, Da	5	2
EVN-A	Jb-1, Ef, Tm-65, Wb, On-85, Tr, Sv, Bd, Zc, Ur	10	4
EVN-B	Jb-1, Ef, Tm-65, Wb, On-85, Tr, Sv, Bd, Zc, Ur, De, Kn, Pi, Da, Cm	15	5

- This error is proportional to source dynamic range so primary beam errors not too severe at low S/N.
- Will become ever more important with increasing VLBI bandwidths and inclusion of sensitive (phased-up) elements e.g. MeerKAT / SKA.
- To correct this effect, we need models of the primary beams!

![](_page_39_Figure_10.jpeg)

WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

![](_page_39_Picture_12.jpeg)

![](_page_39_Picture_13.jpeg)

### **Primary beam models - current status**

- VLBA and GBT estimates exist (e.g. Middelberg+2013)
- Some for e-MERLIN (Wrigley) 2016) but about to be updated for whole array.
- Only a few at 1-2 GHz for the EVN but all is about to change! Accepted proposal (EVN + e-MERLIN joint effort) to map EVN stations.
- Current primary beam models at 1-2 GHz are crude estimates (taking into account blockages etc.; see Radcliffe+18)

![](_page_40_Figure_6.jpeg)

maser source W75N-VLA2. Results expected in Q2 2021.

![](_page_40_Picture_11.jpeg)

### **Primary beam correction schemes**

- With beam models / approximations at hand, how do we apply these corrections for heterogeneous arrays (and wide-field VLBI data)?
- Currently three ways,
  - a. Image plane correction (primarily homogeneous arrays only)
  - **b.** 'Differential' / step-wise primary beam correction
  - c. uv-plane correction i.e. a-projection

![](_page_41_Picture_12.jpeg)

### a. Image plane correction

• Can calculate total power beam,  $P_{\rm T}$ , for heterogeneous array via,

![](_page_42_Figure_3.jpeg)

- and divide subsequent image by  $P_{\rm T}.$
- Provides a scalar shift in the image plane (partially fixing flux densities) but **does not** correct for the direction-dependent antenna independent errors.
- You can fix amplitude errors for some sources via self-calibration but crucially not all.

![](_page_42_Figure_9.jpeg)

![](_page_42_Picture_10.jpeg)

![](_page_42_Picture_11.jpeg)

## b. 'Differential' / step-wise primary beam correction

Effectively does the following to each baseline,

$$V_{pq,\text{obs}}(l_{\text{pc}}, m_{\text{pc}}) = \frac{V_{pq,\text{obs}}}{E_p(l_{\text{pc}}, m_{\text{pc}})E_q^H(l_{\text{pc}}, m_{\text{pc}})}$$

- (Sometimes conducted)  $\rightarrow$  outside of the phase centre centre, calculate error difference plane to recover true fluxes.
- Note that this only perfectly corrects amplitude errors at centre of each phase centre.

• Correct each phase centre in *uv* plane using gain table with a singular value for each antenna's primary beam voltage, evaluated at centre of the phase centre (where  $l = l_{pc}$  and  $m = m_{pc}$ ).

between real primary beam response and *uv* corrected response, and correct in the image

• Residual amplitude errors proportional to  $\left. 
abla \left[ m{E}_p m{E}_q^H 
ight] 
ight]$  , distance from centre of phase centre & primary beam model errors **but errors are much smaller** than image plane only correction!

![](_page_43_Picture_13.jpeg)

![](_page_43_Figure_14.jpeg)

![](_page_43_Picture_15.jpeg)

## b. 'Differential' / step-wise primary beam correction

• 12 hour simulated EVN observation (central rms  $\sim 4 \,\mu Jy \, beam^{-1}$ )

![](_page_44_Figure_3.jpeg)

**JACK RADCLIFFE** 

![](_page_44_Figure_6.jpeg)

![](_page_44_Picture_7.jpeg)

![](_page_44_Picture_8.jpeg)

## **b.** 'Differential' / step-wise primary beam correction

- This is the current method used in published wide-field VLBI studies.
- AIPS
  - For VLBA AIPS task CLVLB (Middelberg+13, Herrera-Ruiz+18)
  - For EVN (using Parseltongue) <u>https://</u> github.com/jradcliffe5/EVN\_pbcor (Radcliffe+18) or given by the EVN pipeline output.
- CASA conversions currently being tested.

![](_page_45_Figure_10.jpeg)

WIDE-FIELD IMAGING - CASA-VLBI WORKSHOP 2020

![](_page_45_Picture_12.jpeg)

![](_page_45_Picture_13.jpeg)

## c. *a*-projection

\*Same 12 hour simulated EVN observation (central rms ~ 4  $\mu$ Jy beam<sup>-1</sup>)

- New method corrects for primary beam response while gridding visibilities.
- Implemented in the Image Domain Gridder (IDG) as part of the wsclean imaging package.
- Will correct for primary beam effects with smaller error than other methods.
- Method can also implement:
  - More complex beams (e.g. true frequency dependence - i.e. not  $1/\lambda$ , beam rotation of sidelobes etc.)
  - And other direction-dependent effects (e.g. pointing errors, TEC dispersion etc.)

All these correction schemes implemented / planned in cm-VLBI pipeline (not native to CASA)

## **And finally!**

#### Key takeaways

- Wide-field VLBI has many use cases and could be useful to your science.
- Calibration is simple and additional steps easily parallelised (and becoming user-friendly!)
- Additional calibration techniques applicable to standard VLBI observations e.g. MSSC.
- Final hurdle of primary beam correction of heterogeneous arrays currently being overcome.
