## The LOFAR Clock System

*Peter Maat, Klaas Dijkstra, Gijs Schoonderbeek, Andre Gunst*

- Frequency range:
  - Low band: 10 - 90 MHz
  - High band: 110 - 250 MHz
- 38 station in the Netherlands
- 12 European stations

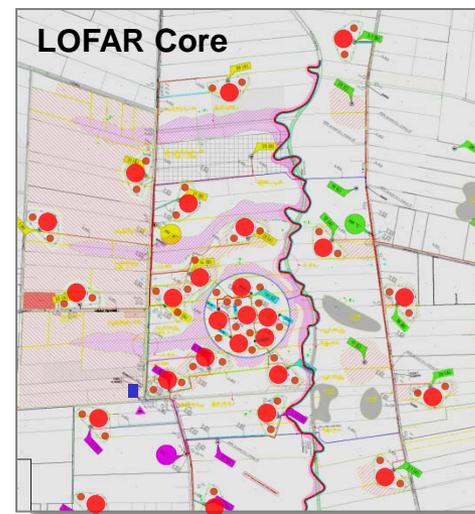

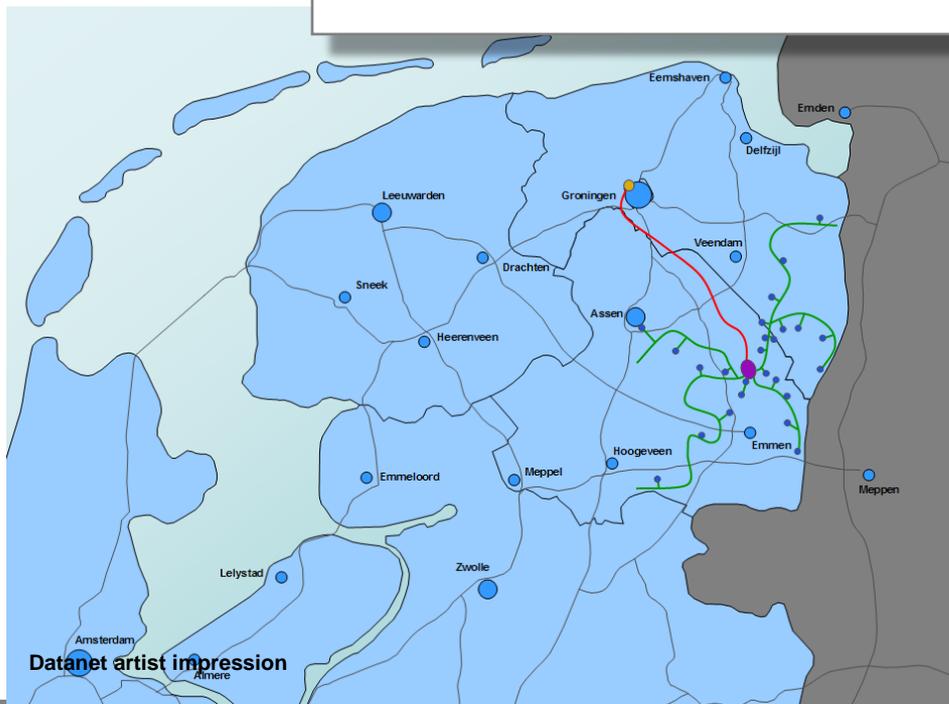

## Core Stations:

- 24 Stations
- Intra-Core distance < 10 km

## Remote Stations:

- 14 Stations
- Distance to LOFAR – Core < 80 km

### Approach:

- ◆ Realise connectivity via NRENs
- ◆ Connection to CEP via Dutch NREN
- ◆ Transportation via 10 Gb/s lightpaths

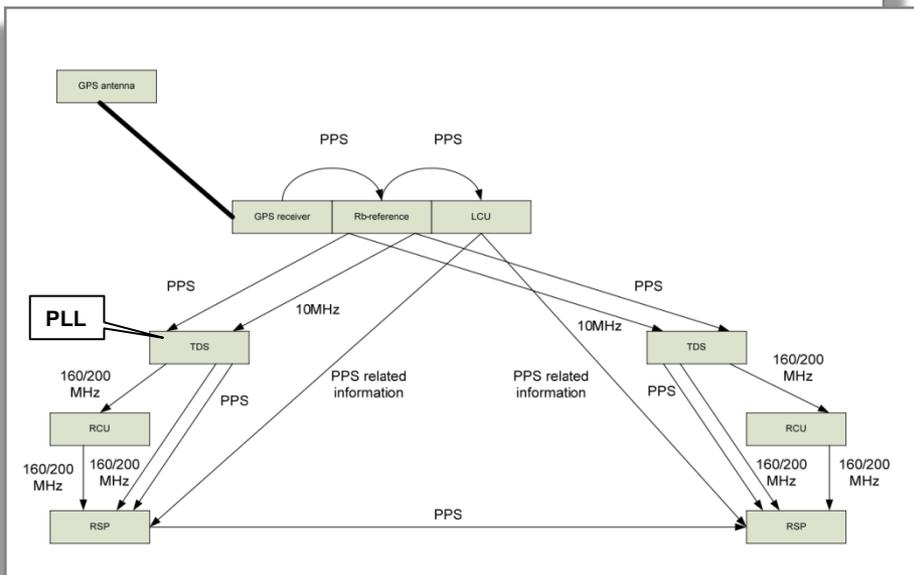

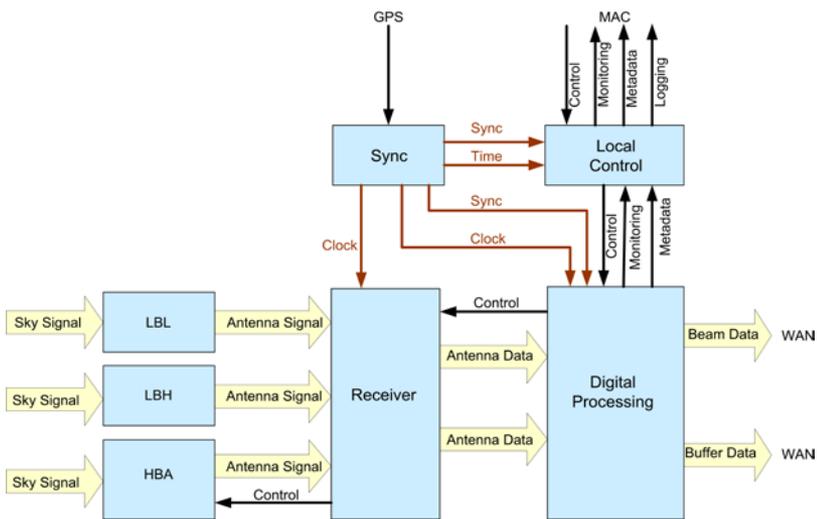

Onsala

Effelsberg

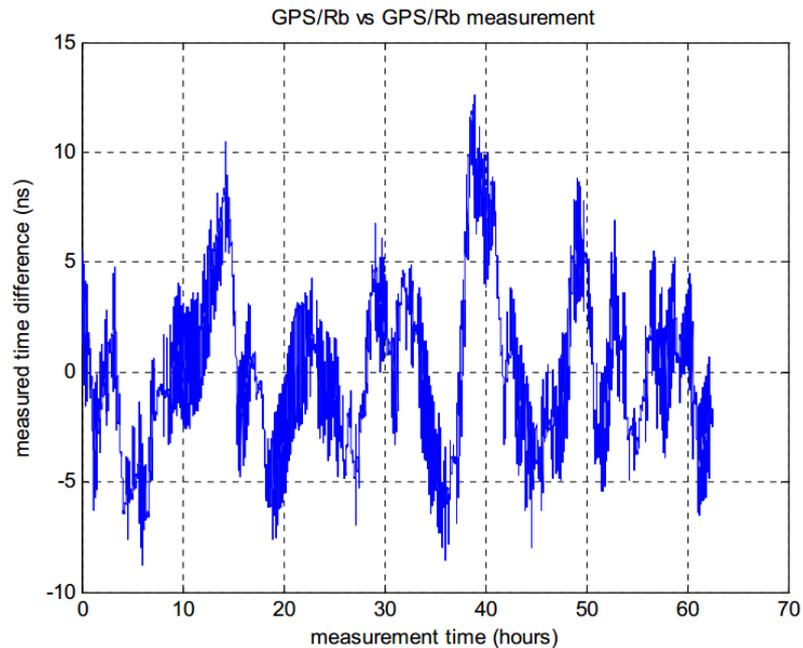

Each LOFAR station has an independent clock system:

- Rubidium reference clock
- Controlled by a GPS receiver

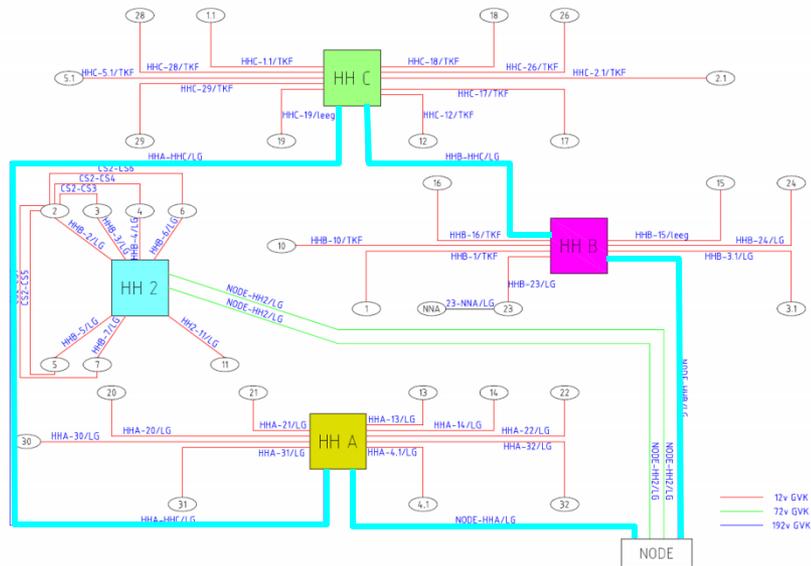

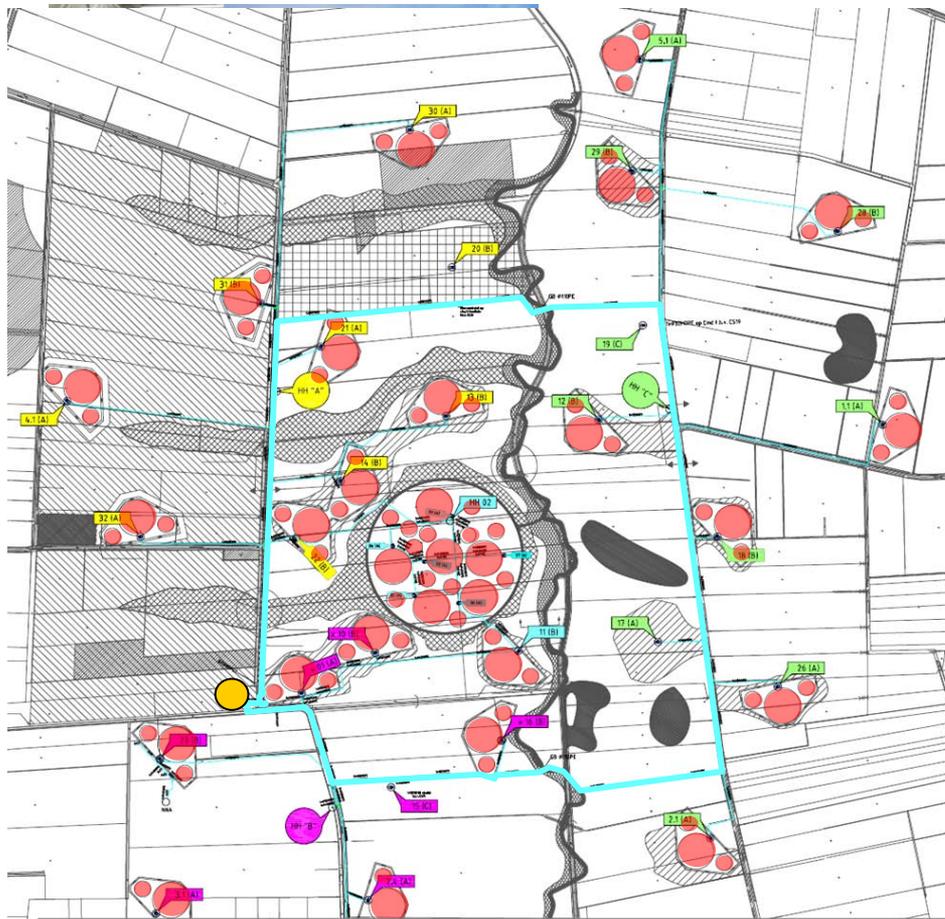

Offset between two GPS/Rb clocks over a 2.5 day period

- ◆ Maximum offset of 10 ns
- ◆ RMS offset of 3.5 ns

➔ Improved stability needed for e.g. tied array observations

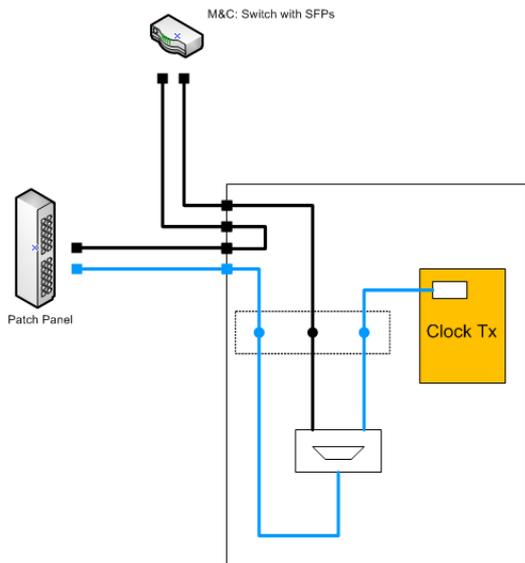

Data links per station:

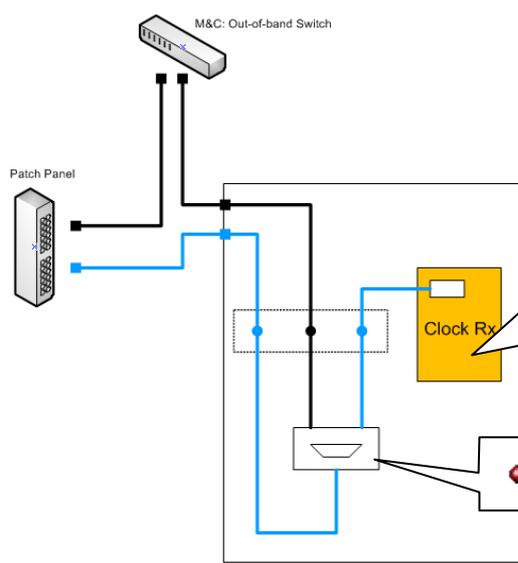

- Observation data: 10Gbase-LX (10 km 10GbE, 1310 nm)
- Monitoring & Control: 100Base-LX (10 km, 100MbE, 1310 nm)

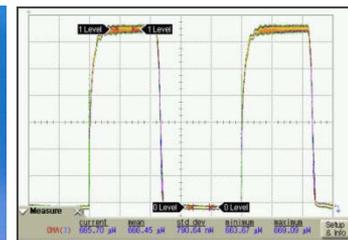

@ CN

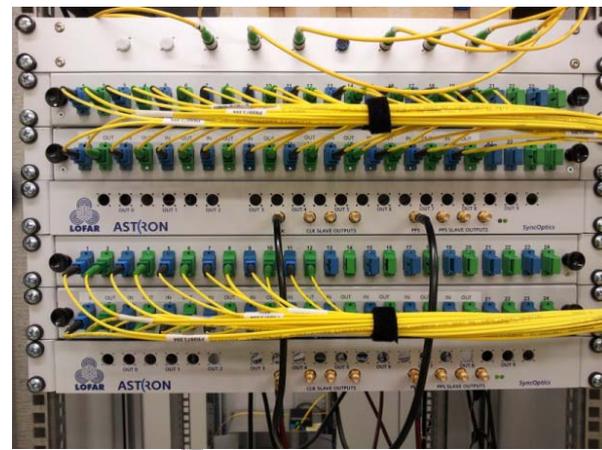

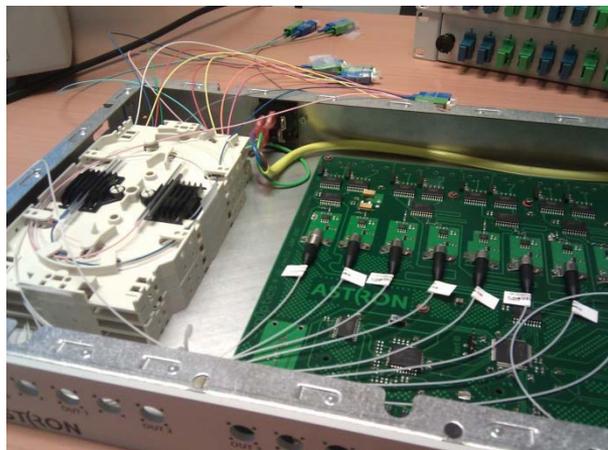

@ Station

- DFB / PIN detector
  - single mode, 1550 nm
  - 1 GHz bandwidth

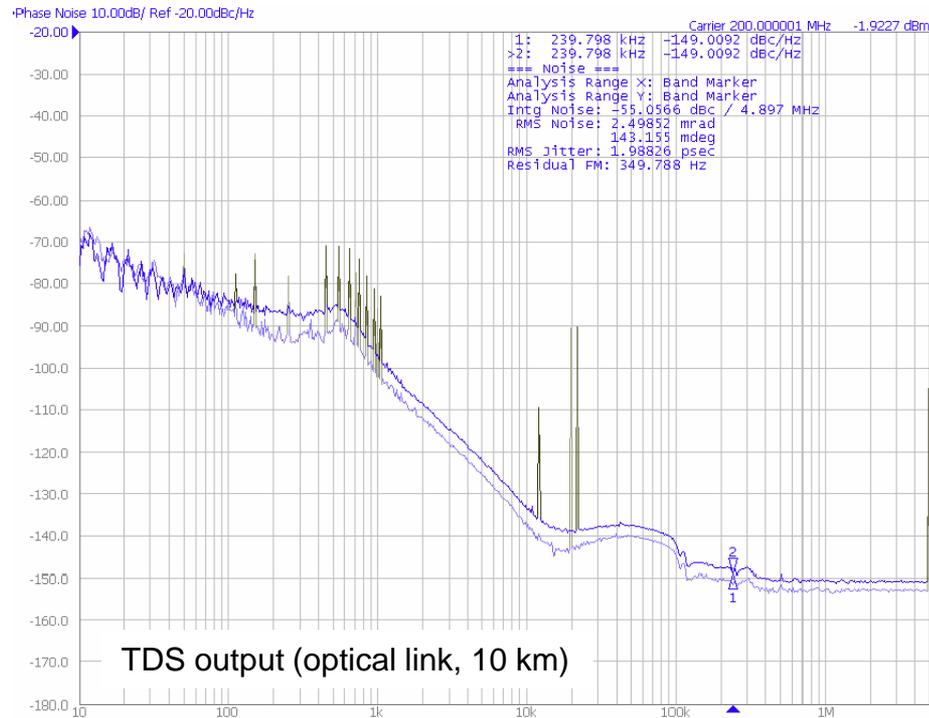

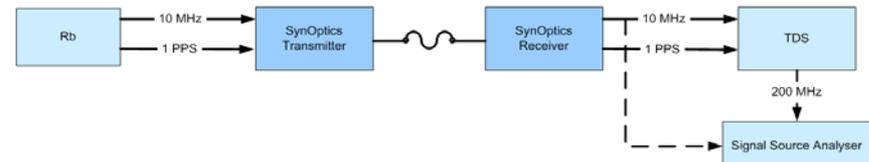

- 1310/1550 nm (de)mux

### 200 MHz phase noise with short and 10 km optical cable

- TDS output (Rb clock), rms jitter: 0.5 ps
- TDS output (optical link b-b), rms jitter: 1.5 ps
- TDS output (optical link, 10 km), rms jitter: 2.0 ps

- Temperature effects not taken into account!

## Influence of temperature:

- Receiver: 20 ps/°C
- Transmitter: 40 ps/°C
- Optical Fiber: 466 ps/°C

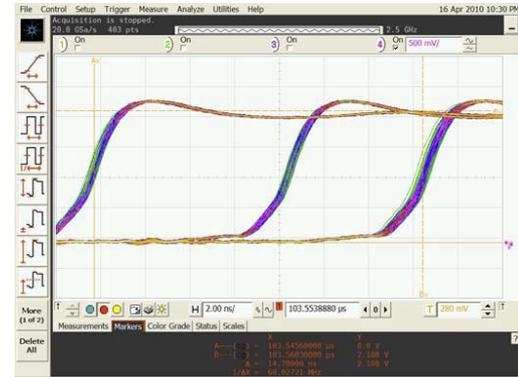

➔ Phase change due to receiver & transmitter: 5°/°C @ 240 MHz

Receiver

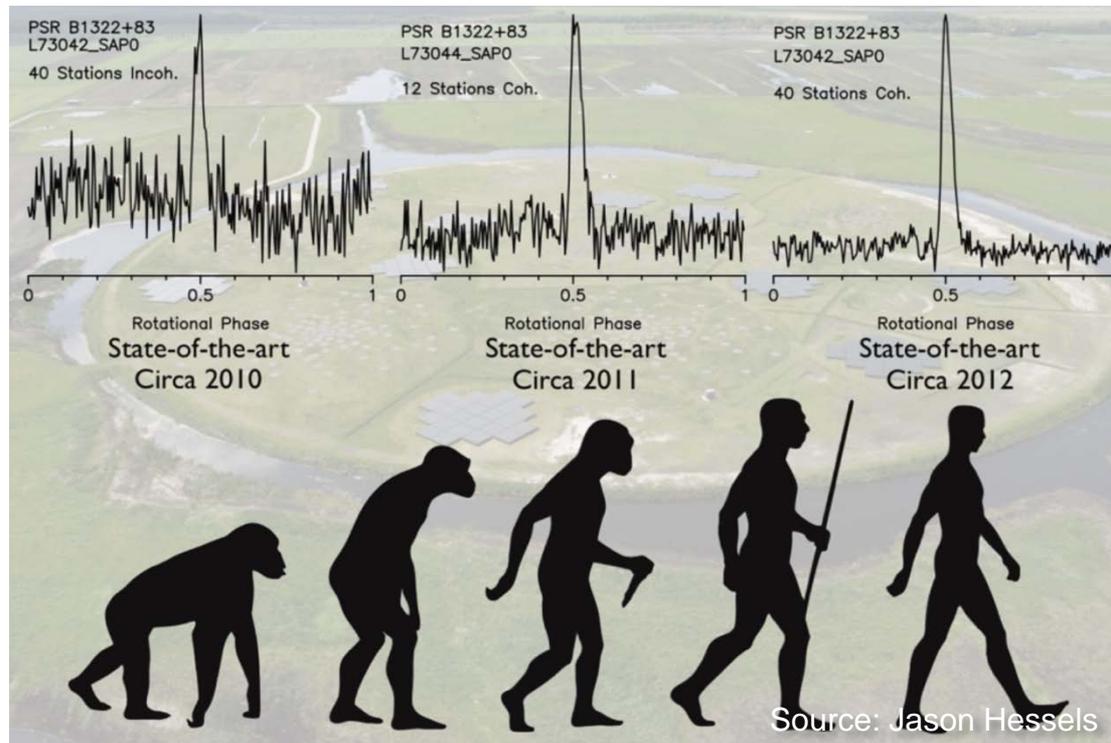

Transmitter

Optical fiber

→ Time difference ~ 1ns

### Possible next steps:

- Reduction of the influence of temperature fluctuations on the phase to reduce calibration effort
- Central clock beyond the LOFAR Core
